# Halo population from beam scraping

# Beam lost at each step

# Affected pbar train has lower halo population

# Diffusion rate vs. amplitude from time evolution of local losses

Collimator “baby steps” with e-lens on/off done yesterday (EOS 8508).  
Data being analyzed.

Started looking at effect of HEBC on loss spikes.

Need opportunistic extinction measurement to determine collimator distance from beam axis.

1 transfer at 150 GeV should work.
